DESCRIPCIÓN

5

La presente invención se refiere a un método *in vitro* para el diagnóstico o pronóstico de una enfermedad genética o el diseño de tratamiento en un sujeto con una enfermedad genética caracterizado por comprender la detección de cambios en el número de copias de regiones cromosómicas concretas. Por tanto, la invención se 10 podría encuadrar en el campo del análisis genético.

ANTECEDENTES DE LA INVENCIÓN

La aparición de sistemas de análisis genómico masivo han permitido analizar en un 15 sólo experimento el estado de miles de regiones a lo largo del genoma humano contribuyendo al conocimiento del componente genético de diversas patologías. La miniaturización de los sistemas de hibridación ha convertido a los *arrays* en una herramienta de alto rendimiento para el estudio de enfermedades congénitas y genéticas con afectación de uno o más cromosomas, con alteraciones de tamaños 20 diversos, conteniendo la mayoría de ellas varias decenas, cientos o incluso miles de genes afectados que ponen de manifiesto la necesidad del uso de herramientas de estudio masivo (Fröhling S *et al.*, 2008, N Engl J Med. 359(7):722-34). Los *arrays* identifican cambios en el número de copias a lo largo de todo el genoma tanto 25 ganancias como pérdidas incluyendo delecciones homocigotas y amplificaciones génicas. El conocimiento de las alteraciones en el ácido desoxirribonucléico (ADN, cambios significativos, heterogéneos y recurrentes con posiciones concretas en las regiones cromosómicas implicadas) hace necesario su estudio al establecerse su valor diagnóstico y pronóstico, proporcionando factores objetivos para clasificar enfermedades así como para controlar e indicar tratamientos específicos, al 30 descubrirse genes dianas y terapias específicas (Albertson DG *et al.*, 2003, Hum Mol Genet. 12, 2:R145-52; Zhao X *et al.*, 2004, Cancer Res. 64(9):3060-71). Entre los métodos para el análisis del genoma se encuentran la hibridación genómica comparada (CGH), la hibridación *in situ* (FISH), *arrays* con cromosomas artificiales de levadura (“Bacterial Artificial Chromosome” BAC *arrays*), técnicas basadas en la

reacción en cadena de la polimerasa (PCR) y el cariotipo. El conocimiento genético se ha fundamentado en los hallazgos de análisis citogenéticos convencionales y métodos moleculares, que son técnicas con limitaciones y ventajas, que pueden ser complementarias. El cariotipo tiene una baja resolución, es necesario realizar previamente cultivos celulares que alarga el tiempo de diagnóstico, selecciona clones con ventaja proliferativa, analiza un bajo número de células y existe subjetividad en la interpretación pero permite el estudio global del genoma. La CGH convencional informa del contenido del ADN de varios miles o millones de células pero presenta inespecificidad en la hibridación por el tamaño de las sondas. La FISH es muy específica, se puede realizar en interfase y/o metafase pero es parcial, dirigida a zonas del genoma y limitada generalmente a tres fluorocromos y sus combinaciones. Por otra parte, la PCR es económica pero parcial y dirigida a regiones concretas en cada análisis. El uso de *arrays* resuelve algunas de estas limitaciones al proporcionar mayor resolución, mayor número de regiones en cada estudio y objetividad en el análisis genético.

Existen diversos *arrays* para estudiar globalmente el genoma que comprenden miles de sondas y la tendencia es aumentar las sondas contenidas en los mismos. Así de *arrays* que contenían 77 sondas subteloméricas para identificación de retraso mental, se pasó a *arrays* de expresión con 20.000 a 50.000 sondas y/o *arrays* que detectan polimorfismos con medio millón ó 1.800.000 sondas. Análisis comparativos de estas plataformas muestran la sensibilidad y especificidad de los distintos *arrays* (Fadista J *et al.*, 2012, PLoSOne. 7,2:e31025). Los *arrays* comerciales disponibles en la actualidad tienen en común el elevado número de secuencias pero características diferentes como son: el método de producción, distintos tamaños en las secuencias inmovilizadas (entre 25-80 nucleótidos) y el tipo de marcaje para la hibridación (único o doble). La fabricación estandarizada de estos *arrays* ha ido completando y mejorando formatos sucesivos y se han diseñado con fines diferentes: estudio de variaciones génicas, análisis preimplatación de embriones, microdelecciones, genotipado, estudio de neoplasias hematológicas, análisis de genes supresores y oncogenes y análisis de metilación (Curtis C *et al.*, 2009, BMC Genomics. 10:588-610; Miller DT *et al.*, 2010, Am J HumGenet. 286(5):749-64; Crespo I *et al.*, 2011, J Mol Diagn.13(6):634-47 y Tabernero MD *et al.*, 2012, Genes Chromosomes Cancer. 2012,51(6):606-17).

El alto número de sondas inmovilizadas en los distintos *arrays* diseñados hace imprescindible el uso de herramientas informáticas para obtener la gran cantidad de información contenida. Los análisis matemáticos identifican las variaciones en toda la extensión del genoma, y la dependencia de recursos bioinformáticos tienen un impacto

5 no despreciable en la incorporación al diagnóstico clínico de esta tecnología. Actualmente, los *arrays* contienen millones de sondas de oligonucleótidos con un importante coste de fabricación y de recursos en el análisis de la información que contienen, pero no existe un *array* simple y específico para analizar en muestras de ADN el número de copias de los 24 cromosomas en toda su extensión con utilidad en

10 cáncer, enfermedades genéticas y/o hereditarias u otras patologías. Por lo tanto es necesario un *array* de menor tamaño que los actuales, que siga siendo informativo para detectar el número de copias de todos los cromosomas y las regiones de interés en enfermedades genéticas.

15 DESCRIPCIÓN DE LA INVENCIÓN

La presente invención se refiere a un método *in vitro* para el diagnóstico o pronóstico de una enfermedad genética o para el diseño de un tratamiento personalizado en un sujeto con una enfermedad genética mediante la detección de cambio en el número de

20 copias de regiones cromosómicas concretas que proporcionan información sobre todos los cromosomas. La invención también se refiere a un *array* de búsqueda de alteraciones útil como herramienta diagnóstica y/o pronostica de alteraciones genéticas y para la individualización de tratamiento en pacientes que proporciona información sobre todos los cromosomas. En adelante nos referiremos a este método como al “método primero de la invención”. Tal y como se ha explicado anteriormente, las
25 regiones cromosómicas (loci) aquí descritas se denominan en la presente invención “regiones cromosómicas de la invención”.

Una realización preferida del primer aspecto de la invención se refiere al método donde la enfermedad genética es cáncer o una enfermedad congénita.

30

El término cáncer (o tumor) se refiere en la presente invención a la enfermedad que se asocia a la presencia de células que poseen características de células tumorales conocidas por el experto en la materia, como son la proliferación sin control, inmortalidad, inducción de angiogénesis, resistencia a la muerte celular programada y

potencial metastásico (Hanahan D *et al.* 2011 Cell 144(5):646-74). En la presente invención el término “cáncer” incluye tumores primarios (con células del mismo origen del lugar donde se encuentran) o metastásicos (con células de distinto origen del lugar en el que se encuentran) y también incluye los tumores en cualquiera de sus grados 5 de afectación o estadio.

Una realización aún más preferida del primer aspecto de la invención se refiere al método donde el cáncer es cáncer del sistema nervioso central, cáncer de colon, cáncer de pulmón, cáncer de mama, cáncer de próstata, cáncer de vejiga, leucemias 10 linfáticas crónicas, leucemias linfáticas agudas, mieloma múltiple, síndrome mielodisplásico (por ejemplo, anemia refractaria y síndrome mielodisplásico con delección 5q). Preferentemente, el cáncer del sistema nervioso central es glioma (bajo y alto grado), meningioma benigno, meningioma maligno, oligodendrogioma o glioblastoma multiforme. En la presente invención el término “glioma” incluye tumores 15 de bajo y alto grado.

Se entiende como enfermedad congénita aquella enfermedad que se manifiesta desde el nacimiento, ya sea producida por un trastorno durante el desarrollo embrionario o como consecuencia de un defecto hereditario. Preferentemente la enfermedad 20 congénita es síndrome de Down, síndrome de Edwards o síndrome de Patau.

El término “*in vitro*” se refiere a que el método de la invención se realiza fuera del cuerpo del sujeto.

25 El término “sujeto” se refiere a un individuo, preferentemente humano, que puede presentar una alteración genética y puede haber sido o no diagnosticado de una enfermedad genética. En la presente invención los términos “sujeto” “individuo” y “paciente” se utilizan indistintamente.

30 En la presente invención se entiende por “ganancia cromosómica” el aumento en el número de copias de material genético en una región cromosómica comparado con un control. Por “pérdida cromosómica” se entiende la disminución del número de copias de una región cromosómica comparada con un control. En la presente invención se entiende como “alteración génica” o “alteración genética” tanto una ganancia como

una pérdida genética. Como “control” se entiende una muestra de un individuo que no presenta alteración genética.

El término “muestra” se refiere a una “muestra biológica” y se refiere a cualquier muestra que permita obtener ADN del individuo del que se ha obtenido dicha muestra, e incluye, pero sin limitarnos, tejidos y/o fluidos biológicos de un individuo, obtenidos mediante cualquier método conocido por un experto en la materia que sirva para tal fin. La muestra biológica podría ser, por ejemplo, pero sin limitarse, un tejido o una muestra de fluido, como sangre, plasma, suero, mucosa oral, lavado broncoalveolar, linfa, fluido ascítico, líquido pleural u orina. Asimismo, la muestra biológica puede ser, por ejemplo, pero sin limitarse, fresca, congelada, fijada o fijada y embebida en parafina.

De una muestra biológica se extrae el material genético mediante cualquier método conocido por el experto en la materia. En la presente invención como material genético se entiende ADN.

Las “regiones cromosómicas de la invención” son regiones que se sitúan en los cromosomas 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, X 20 o Y, en el brazo corto (p) o en el brazo largo (q) del cromosoma.

Se entiende por enfermedad “genética” aquella que está asociada a una alteración en el material genético presente en un sujeto.

Un segundo aspecto de la invención se refiere a un método *in vitro* para el diagnóstico o pronóstico de una enfermedad genética o para el diseño de un tratamiento personalizado en un sujeto con una enfermedad genética caracterizado por comprender los siguientes pasos:

En adelante nos referiremos a éste como al “segundo método de la invención”.

El término “diagnóstico” en la presente invención se refiere a la capacidad de detectar una enfermedad genética en un sujeto.

30 El término “pronóstico” en la presente invención se refiere a la capacidad de detectar una alta o baja probabilidad de desarrollar una enfermedad genética aún cuando en el momento del diagnóstico no presenten dicha patología. También se refiere a la capacidad de predecir la evolución de un paciente con una determinada enfermedad (también denominada patología).

Se entiende por “tratamiento” al conjunto de medios que se emplean para curar o aliviar una enfermedad.

- 5 Con “diseño de un tratamiento personalizado” se entiende la determinación de la necesidad de un individuo de recibir un determinado tratamiento en base a la detección de una ganancia y/o pérdida cromosómica en las regiones cromosómicas de la invención, es decir, con el método de la invención se clasifica al individuo en un grupo de individuos con necesidad de tratamiento específico para una determinada
- 10 enfermedad o en un grupo de individuos que no presentan necesidad de tratamiento específico para la misma.

Se entiende por niveles “estándar” aquellos que provienen de una muestra control que no contiene alteración genética en la región cromosómica a comparar.

- 15 Una realización preferida del segundo aspecto de la invención se refiere al método donde en el paso (d) y el paso (e) la ganancia o pérdida genética es una pérdida o ganancia de al menos un cromosoma entero, de al menos uno de los brazos de un cromosoma o de al menos una región cromosómica de al menos uno de los brazos de
- 20 un cromosoma.

- 25 Otra realización más preferida se refiere al método del segundo aspecto de la invención donde la detección y/o cuantificación del paso (a) se realiza mediante la detección y/o cuantificación de al menos un gen que se encuentre localizado en las regiones cromosómicas descritas en el paso (a).

- 30 Una realización aún más preferida del segundo aspecto de la invención se refiere al método donde los genes son los genes de la tabla 1. En adelante nos referiremos a ellos como a los “genes de la invención”. Los genes de la invención se encuentran localizados en las regiones cromosómicas de la invención.

Tabla 1. Genes localizados en las regiones cromosómicas de la invención: se proporciona el número de identificación de los 3920 genes “Entrez Gene ID” del “National Center for Biotechnology Information (NCBI)” Bethesda, Maryland, USA.

Una realización aún más preferida del segundo aspecto de la invención se refiere al
5 método donde la detección y/o cuantificación del paso (a) se realiza mediante la
detección y/o cuantificación de al menos un polimorfismo genético. Una realización
aún más preferida se refiere al método donde la detección y/o cuantificación del paso
(a) se realiza mediante la detección y/o cuantificación de los polimorfismos de la tabla
2. En adelante nos referiremos a ellos como a los “polimorfismos de la invención”. Los
10 polimorfismos de la invención se encuentran localizados en las regiones
cromosómicas de la invención. Los polimorfismos podrían ser polimorfismos
correlativos a los indicados con un intervalo de más menos 200pb.

Otra realización preferida del segundo aspecto de la invención se refiere al método donde la enfermedad genética es cáncer o una enfermedad congénita. Preferentemente el cáncer es cáncer del sistema nervioso central, cáncer de colon,
10 cáncer de pulmón, cáncer de mama, cáncer de próstata, cáncer de vejiga, leucemia linfática crónica, leucemia linfática aguda, mieloma múltiple o un síndrome mielodisplásico. Más preferentemente el cáncer del sistema nervioso central es glioma (bajo y alto grado), meningioma benigno, meningioma maligno, oligodendrogioma o glioblastoma multiforme. Preferentemente la enfermedad congénita es síndrome de
15 Down, síndrome de Edwards o síndrome de Patau.

Una realización preferida del método primero o del método segundo de la invención se refiere al método donde la detección de la ganancia y/o pérdida cromosómica se realiza mediante hibridación con sondas de ácido desoxirribonucleico (ADN).
20 Preferentemente el número de sondas se sitúa entre 10.000 y 20.000 sondas diferentes, más preferentemente el número de sondas se sitúa entre 14.000 y 15.000 sondas diferentes. En otra realización aún más preferida las sondas tienen entre 20 y 200 pares de bases (pb). Las sondas pueden ser sondas polimórficas o sondas no polimórficas. El término “sondas polimórficas” se refiere a sondas que detectan
25 polimorfismos del tipo “single nucleotide polymorphism” o SNP. Por lo tanto, una realización aún más preferida del método primero o del método segundo de la invención se refiere a los métodos donde las sondas detectan al menos un polimorfismo genético, preferiblemente detectan los polimorfismos señalados en la tabla 2. Las sondas no polimórficas detectan material genético que no comprende
30 polimorfismos. Las sondas pueden estar repetidas.

El término “polimorfismo genético” se refiere a una variación en la secuencia de nucleótidos de la cadena de ácido desoxirribonucleico (ADN o DNA, “desoxirribonucleic acid”) que tiene al menos una frecuencia del 1% en los individuos

de una población. Los polimorfismos genéticos pueden ser variaciones de uno o varios nucleótidos. El polimorfismo de un solo nucleótido, “*single nucleotide polymorphism*” o SNP, generalmente da lugar a dos alelos distintos. Los SNPs o polimorfismos pueden contener información sobre la variación de un solo polimorfismo o la información de un 5 haplotipo si son SNP etiquetas o “tag-SNP”. En la presente invención los términos “polimorfismo” y “SNP” se utilizan de manera indistinta.

Los polimorfismos Tag-SNPs son polimorfismos marcadores de una región genómica que se encuentra dentro de un determinado bloque haplotípico. Cualquier variante 10 genética que se encuentre dentro del mismo bloque haplotípico que los Tag-SNPs se heredará conjuntamente con éstos con una alta probabilidad. Es decir, los polimorfismos dentro de un bloque haplotípico están en desequilibrio de ligamiento (de Bakker, P.I.W., y cols. 2005. *Nature Genetics*, 37(11):1217-1223).

15 En la presente invención nos referimos a “haplotipo” como un conjunto de polimorfismos (SNPs) que se heredan en bloque.

Los términos “polinucleótido”, “secuencia nucleotídica”, “secuencia de nucleótidos”, “ácido nucleico” y “oligonucleótido” se usan aquí de manera intercambiable, y se 20 refieren a una forma polimérica de nucleótidos de cualquier longitud, que pueden estar, o no, química o bioquímicamente modificados.

Otra realización aún más preferida se refiere a los métodos donde las sondas se sitúan en un soporte sólido. Los soportes sólidos que se pueden utilizar son los 25 conocidos por el experto en la materia, por ejemplo vidrio, nitrocelulosa o nylon.

Con el método de la invención, se puede realizar el análisis de no sólo una única muestra, sino de varias muestras en un mismo soporte sólido debido a la menor densidad (se pueden incluir varias muestras entre 2 a 10 pacientes en un mismo 30 soporte o portaobjetos) pero manteniendo la capacidad de análisis global del genoma, siendo posible el análisis de cada muestra de forma individual. La presente invención constituye por lo tanto una mejora y una simplificación con respecto a los métodos conocidos hasta ahora.

Las sondas se pueden modificar posteriormente a su fijación al soporte sólido mediante la adición de fluorocromos o moléculas quimioluminiscentes por los métodos conocidos por cualquier experto en la materia. Por este motivo, otra realización aún más preferida del método primero y segundo de la invención se refiere a ambos 5 métodos donde las sondas están marcadas con fluorocromos, por ejemplo como biotina, estreptavidina-ficoeritrina.

El término “hibridación”, tal y como se utiliza en la presente descripción, se refiere al apareamiento de dos moléculas de ADN de cadena simple complementarias para dar 10 una molécula de doble cadena. Preferiblemente, la complementariedad es del 100%. Esto es, en la región de complementariedad cada nucleótido de una de las dos moléculas de ácido nucleico puede formar enlaces de hidrógeno con un nucleótido presente en la otra molécula de ácido nucleico. Sin embargo, aquéllos con una experiencia normal en el campo reconocerán que dos moléculas de ácido nucleico que 15 posean una región con complementariedad menor al 100% también pueden hibridar.

El término “nucleótido”, tal y como se utiliza en la presente descripción se refiere a un molécula orgánica formada por la unión covalente de una pentosa, una base nitrogenada y un grupo fosfato. El término nucleótido incluye desoxirribonucleósidos 20 trifosfato como, por ejemplo, pero sin limitarse, dATP, dCTP, dITP, dUTP, dGTP, dTTP, o derivados de los mismos. El término nucleótido incluye también dideoxirribonucleósidos trifosfato (ddNTPs), como por ejemplo, ddATP, ddCTP, ddGTP, ddITP, ddTTP o derivados de los mismos.

- 25 De acuerdo con la presente invención un “nucleótido” puede ser marcado o etiquetado mediante técnicas bien conocidas en el estado de la técnica. Etiquetas detectables incluyen, por ejemplo, isótopos radiactivos, etiquetas fluorescentes, etiquetas quimioluminiscentes, etiquetas bioluminiscentes o etiquetas enzimáticas.
- 30 Las sondas deben respetar las posiciones físicas que se muestran la tabla 3 en cada cromosoma, con un intervalo de \pm entre 80 a 200 pares de bases (es decir que la distancia entre una sonda y otra similar es de 100 pares de bases). Las posiciones físicas se señalan a continuación (“Cr” se refiere a “cromosoma”):

Tabla 3. Posiciones físicas que deben cubrir las sondas empleadas en el *array* con un intervalo de más menos 200pb (Cr.: cromosoma).

EJEMPLO

A continuación se ilustrará la invención mediante unos ensayos realizados por el inventor, que demuestran la eficacia del método de la invención la identificación de
5 alteraciones en el número de copias en los 24 cromosomas

Ejemplo 1: Obtención del método de la invención de detección de cambio de número de copias en todos los cromosomas en tumores del sistema nervioso central.

10

Se estableció el número de copias y los perfiles de cada cromosoma (Figura 1 y 2) en tumores del sistema nervioso central, meningiomas benignos y malignos, y glioblastomas multiformes (GBM) detectando las pérdidas (Figuras 3 y 4) de material genético de distintos tamaños que van desde la afectación de la totalidad de un
15 cromosoma, uno de sus brazos afectados, o delecciones intersticiales, así como información de genes afectados por delecciones (homocigotas y/o heterocigotas) (Figura 5), amplificaciones génicas (Figura 6) y ganancias (Figuras 7 y 8).

20 Se fijaron las posiciones físicas para los 24 cromosomas, utilizando las regiones distales y proximales de ambos brazos de cada cromosoma excluyendo las regiones pericentroméricas y microsatélites que permiten detectar monosomias y poliploidias que afectan a un cromosoma completo o a un brazo entero (brazo p o q del cromosoma) (Figura 2).

25 Para las pérdidas y ganancias intersticiales de gran tamaño (que afectan a la mitad del brazo, a una cuarta parte, o a tres cuartas partes de cada brazo del cromosoma se identifican en cada brazo las zonas afectadas y se utilizan sondas en esas posiciones físicas), así como en las regiones (perdidas y/o ganadas) de tamaño pequeño, regiones comunes y recurrentes detectadas en cada cromosoma que han sido
30 identificadas en diversos tipos de tumores.

Las regiones de amplificación génica y delección homocigota llevan una mayor cobertura, aumentando la densidad de las sondas en las posiciones físicas que ocupan y cubriendo los distintos tamaños de estas alteraciones (Figura 2).

El *array* se estabiliza con sondas en todas las bandas cromosómicas (pueden ser varias sondas). Se seleccionaron 14.933 sondas repartidas en los 24 cromosomas, que son suficientes para identificar las alteraciones del número de copias (Tabla 4)

5

Tabla 4. Número de sondas utilizadas en el nuevo *array* objeto de la invención y su distribución en los 24 cromosomas comparado con dos *arrays* comerciales. (--) significa que no hay sondas para ese cromosoma o ADN y MT significa mitocondrial.

MATERIALES Y MÉTODOS

- 5 El análisis del número de copias de muestras tumorales para conocer las alteraciones genéticas se realizó con ADN genómico (250ng) hibridado sobre arrays comerciales de la casa Affymetrix (Affymetrix Inc, Santa Clara, CA, USA) en dos series de enfermos de nuestro laboratorio: 50 pacientes con meningiomas y 35 glioblastomas con *GeneChip Human Mapping 500K Array Set* y 7 meningiomas y 26 GBM con
- 10 10 *Genome-Wide Human SNP 6.0 Array*. Además se analizó series de arrays de otros autores todos ellos con un porcentaje de llamadas mayor al 92%: 82 meningiomas (GSE 16583, que suman junto a nuestra serie un total de 139 arrays analizados), 8 series con gliomas (bajo y alto grado) (212 arrays), 78 arrays de 4 series de tumores sólidos (colon, pulmón, mama y próstata) y 231 tumores hematológicos: síndrome
- 15 15 mielodisplásico (SMD), leucemia linfática crónica (LLC), leucemia linfoblástica aguda (LLA) y mieloma múltiple (MM) (Tabla 6), depositados en repositorios públicos [*Gene Expression Omnibus* (GEO) del *National Center of Biotechnology*, USA y *ArrayExpress Archive del European Molecular Biology Laboratory* (EMBL) & *European Bioinformatics Institute* (EBI), *Wellcome Trust Genome Campus*, Hinxton, UK].
- 20 20 Los arrays utilizados (Affymetrix) y sus números de catálogo fueron: el *GeneChip® Mapping 100K Set* que contiene 100.000 sondas distribuidas en dos arrays, 520043 *GeneChip Human Mapping 50K Array Xba* y el 520044 *GeneChip Human Mapping 50K Array Hind*. - 25 25 >500.000 sondas distribuidas en dos chips el *GeneChip Human Mapping 250K Nsp Array* referencia 900767 y 520331 *GeneChip Human Mapping 250K Sty Array* y

Genome-Wide Human SNP Array 6.0 con referencia 901182 que contiene más de 1,8 millones de sondas polimórficas y no polimórficas.

Los *arrays* se realizaron según el protocolo recomendado por el fabricante y conocido por el experto en la materia. Tras la hibridación, se lavaron los chips, se marcaron con biotina (*GeneChip® DNA LabelingReagent*), se escanearon usando GeneChip Scanner 3000 y 3000 G7 (Affymetrix Inc.) y se generaron los ficheros (.CEL que contienen la intensidad de cada sonda) con los programa *Affymetrix® GeneChip® Operating Software* (GCOS) y *Affymetrix Command Console® Software* (AGCC).

10

Los programa informáticos utilizados para el análisis fueron: *GenotypingConsole software* (versión 4.1.1.834; Affymetrix Inc.) y *DNA-Chip Analyzer (dChip) software 2010*, del *Dana Farber Institute*, Harvard, MA, USA para el cálculo de los valores del número de copias y su representación de acuerdo a la localización cromosómica. Los datos para cada sonda fueron extraídos del archivo CEL y convertidos en archivos CHP conocido por el experto en la materia. Se utilizaron los siguientes puntos de corte: para la pérdida de material genético valores $\leq 1,30$ y para las ganancias cromosómicas valores $\geq 2,50$. Las amplificaciones y delecciones homocigotas se establecieron cuando el número de copias era >5 para la amplificación génica y $<0,8$ copias para la delección homocigota. En la construcción de los perfiles del número de copias y los idiogramas de cada cromosoma también se utilizó la versión 2.13.1 del programa R (software libre y lenguaje de programación para análisis estadístico y gráfico con comandos escritos ejecutados directamente y funciones estadísticas específicas para el análisis de *arrays*, contenidas dichas funciones en las llamadas 20 librerías) y las herramientas de Bioconductor 2.8, ambos software libres y disponibles en la web. Se estableció el número de copias de cada cromosoma en los 139 *arrays* con meningiomas, 212 *arrays* con gliomas, 78 *arrays* de otros tumores sólidos y 231 tumores hematológicos (Tabla 6), detectando el tipo y extensión de las pérdidas y ganancias de material genético que afectaban a la totalidad de un cromosoma, uno de 25 sus brazos, o delecciones intersticiales (homocigotas y/o heterocigotas) así como amplificaciones génicas.

Para identificar el menor número de sondas necesarias para nuestra invención, se utilizó el programa *Copy Number Analyzer for Genechip (CNAG) 3.3.0.1(Beta)*,

Genome Laboratory, Universidad de Tokio-Japón siguiendo los siguientes pasos (Figura 9):

- 1)- Se localizaron todas las alteraciones y su extensión en cada cromosoma comenzando por las amplificaciones génicas y las delecciones homocigotas, seguidamente las delecciones heterocigotas y cualquier ganancia o pérdida intersticial y sus posiciones concretas en las regiones implicadas en enfermedades diferentes (Figura 2 y Tabla 6). Se seleccionaron las posiciones más distales de las regiones afectadas y los distintos tamaños de cada alteración para cubrir con sondas todas las regiones alteradas, que se localizaban dentro de genes y se evitaron las sondas redundantes. Las herramientas del programa nos muestran las posiciones físicas (inicio y fin) y las sondas implicadas.
- 2)- Se eliminaron sondas sin información incluidas en los *arrays* (sondas sin información de la posición física en ese cromosoma o sin gen asignado).
- 3)- Se eliminaron sondas de las regiones teloméricas y pericentroméricas para evitar hibridación cruzada entre los cromosomas 1, 5 y 19; el cromosoma 13 con el cromosoma 21; y el cromosoma 14 con el cromosoma 22.
- 4)- Se eliminaron las sondas con número de copias 2 (sondas sin alteraciones), como no informativas.
- 5)- Se seleccionaron sondas en todas las bandas cromosómicas para completar el perfil del cromosoma en toda su extensión.
- 6)- Finalmente, se confirmaron los resultados del *array* nuevo diseñado con representaciones graficas de los ideogramas de cada cromosoma comparando las sondas del nuevo diseño versus los dos *arrays* de alta densidad (más de 500.000 sondas) utilizados. Para ello se utilizó el programa R, versión 2.13.1 y la librería “quantsmooth” (librerías o paquete de funciones para el análisis y visualización de los idiogramas y las copias de cada sonda a lo largo de los cromosomas) disponible en el repositorio de Bioconductor que permite visualizar los datos del número de copias de forma gráfica en los cromosomas.

RESULTADOS

Los resultados mostraron que el método de la invención aún teniendo menor número de sondas que los arrays comerciales de alta densidad, muestra igual resultado (detectamos las mismas alteraciones numéricas, ganancias y pérdidas de distintos tipos y extensión en los tumores recogidos en la tabla 6). Se identificaron las aneuploidías de cada cromosoma (cambios en el número de cromosomas) que afectaban a cromosomas completos monosomias y trisomías. Hemos establecido las alteraciones recurrentes, definido sus características y establecido su impacto en el pronóstico tumoral. Encontramos que las monosomias, delecciones y ganancias aparecen en tumores benignos y malignos localizándose en los cromosomas 22, 1, 14, 6, 7 y 18 en los meningiomas y en los gliomas son más frecuentes las ganancias del cromosoma 7 con o sin amplificación del gen EGFR (existen 2 grupos de tumores según presenten o no amplificación de este gen), con pérdidas simultáneas a nivel de 9p (homocigotas y heterocigotas) y pérdidas de cromosoma 10, alteraciones raramente encontradas en gliomas benignos; así como delecciones heterocigotas y otras amplificaciones génicas de distintas extensiones y localizaciones cromosómicas tanto en tumores sólidos como en neoplasias hematológicas, habiéndose conseguido así un método más simple y optimizado que mantiene la especificidad y que resulta informativo para los 24 cromosomas de forma simultánea. Nuestros resultados avalan el método de la invención en diversas enfermedades genéticas: tumores del sistema nervioso, así como en otros tumores sólidos y hematológicos. La comparación del array específico diseñado *versus* arrays de alta densidad muestra todas las alteraciones encontradas con arrays de mayor tamaño (Figura 10).

El análisis de varias series de tumores permitió identificar sus alteraciones genéticas, confirmando los grupos de alteraciones, sus posiciones físicas (especialmente aquellas que son recurrentes), así como los genes que contienen, por tanto los cambios numéricos (pérdidas y ganancias) serían útiles en la clasificación de estas patologías. El array se diseñó con el número mínimo de secuencias sin sondas redundantes, evitado las sondas situadas en regiones pericentroméricas y en los extremos cromosómicos y se registró la marca "FullChromaArray"® para nuestro diseño.

2. Declaración motivada según los artículos 29.6 y 29.7 del Reglamento de ejecución de la Ley 11/1986, de 20 de marzo, de Patentes sobre la novedad y la actividad inventiva; citas y explicaciones en apoyo de esta declaración

La presente solicitud tiene por objeto un método para la detección global de ganancias y/o pérdidas cromosómicas, aplicable tanto al diagnóstico o pronóstico de una enfermedad genética como al diseño de un tratamiento personalizado para un sujeto que padezca dicha enfermedad genética. La invención comprende asimismo un array para llevar a cabo el método.

El documento D01 divulga un array que permite llevar a cabo un método para determinar la existencia de alteraciones genéticas clínicamente relevantes en diferentes partes del genoma (ver resumen; párrafos 11-12, 14-15, 29, 98-99; tablas 1-2).

El documento D02 divulga una lista de las regiones cromosómicas cubiertas por diferentes arrays comerciales que incluyen arrays de baja densidad (ver todo el documento).

El documento D03 tiene por objeto un array útil para el diagnóstico o pronóstico de neoplasias de células B maduras basado en la detección de alteraciones en el número de copias en distintas regiones localizadas en los 22 cromosomas somáticos humanos (ver resumen; párrafos 11-13; tabla 3).

1.- NOVEDAD (Art. 6.1, LP 11/1986).**Reivindicaciones 1-35**

En el estado de la técnica existen numerosos ejemplos de métodos de diagnóstico y/o pronóstico de enfermedades genéticas basados en la detección mediante ensayos de *microarray* de variaciones en el número de copias de diferentes regiones cromosómicas. Sin embargo, ninguno de los documentos D01-D03 considerados divulga métodos de diagnóstico y/o pronóstico de una enfermedad genética, o de diseño de un tratamiento personalizado de un sujeto con dicha enfermedad genética, basados en la detección de ganancias y/o pérdidas cromosómicas en un conjunto de regiones cromosómicas igual al definido en la presente solicitud.

En base a lo anterior, el objeto de las reivindicaciones independientes 1, 6, 22, 27 y 31 y, por extensión el de sus reivindicaciones dependientes 2-5, 7-21, 23-26, 28-30 y 32-35, cumple con el requisito de novedad establecido en el art. 6.1 de la LP 11/1986.

2.- ACTIVIDAD INVENTIVA (Art. 8.1, LP 11/1986).**Reivindicaciones 1-35**

El documento del estado de la técnica que se ha considerado más próximo al objeto de las reivindicaciones independientes 1, 6, 22, 27 y 31 es D01. Dicho documento se refiere a un método de diagnóstico de enfermedades genéticas, incluyendo cáncer. El método se basa en la detección global de variaciones en el número de copias de un conjunto de *loci* localizados en los 24 cromosomas humanos. Estos *loci* han sido seleccionados por proporcionar resultados fiables y clínicamente relevantes en un ensayo de array mejorado en el que se han eliminado regiones de bajo valor informativo. Como ya se ha indicado, este conjunto de *loci* de D01 no coincide con el conjunto seleccionado en la invención objeto de la presente solicitud, incluyendo esta última un número notablemente mayor de regiones cromosómicas con valor informativo desde el punto de vista clínico en todos los cromosomas, excepto en el caso de los cromosomas 19 e Y. Por otra parte, al comparar las regiones cromosómicas cubiertas por los arrays divulgados en D02 y D03 con las de la presente solicitud se observa también que el número de regiones informativas seleccionadas es claramente menor en D02 y D03, si bien en algún caso, como ocurre en D02, se observa una coincidencia con la presente invención en ciertas regiones seleccionadas, como por ejemplo las correspondientes a los cromosomas 22, X e Y.

El problema técnico que viene a resolver la invención objeto de la presente solicitud es la carencia de un *array* de menor tamaño que los existentes en el estado de la técnica que al mismo tiempo siga siendo de interés para detectar variaciones en el número de copias de todos los cromosomas relevantes en enfermedades genéticas. Para resolver este problema, la inventora ha llevado a cabo un trabajo de investigación que le ha permitido llegar al diseño de un *array* de baja densidad que emplea un número de sondas notablemente menor que el de otros *arrays* existentes de alta densidad, pero que al mismo tiempo demuestra mantener un valor informativo desde el punto de vista clínico similar a éstos últimos. Este resultado no hubiera podido ser alcanzado de forma obvia para un experto en la materia meramente a partir de las enseñanzas de D01-D03, tomados éstos por separado o de forma combinada.

En base a lo anterior se considera que el objeto de las reivindicaciones independientes 1, 6, 22, 27 y 31, y lógicamente el de sus reivindicaciones dependientes 2-5, 7-21, 23-26, 28-30 y 32-35, satisface el requisito de actividad inventiva del art. 8.1, LP 11/1986.
